University of Helsinki / Department of Mathematics and Statistics SCIENTIFIC COMPUTING Exercise 6, 15.10.2012

- **N.B.** The files mentioned in the exercises (if any) are available on the course homepage
- 1. The Senior Researcher studies the intelligence quotient (IQ) of the Ubuntu tribe in the Third World. The results of an IQ test are listed here:

IQ -range	# of s	amples	Normalized	samples
61-70	89			
71-80	106			
81-90	84			
91 -100	94			
101-110	35			
111-120	23			
121-130	11			
131-140	1			
141-150	2			

Compute the mean μ and the variance σ^2 of the sample. Fill in the third column, for each row the normalized sample is # of samples divided by the total number of samples.

2. The daily temperature data is observed and the results appear in the table below. Create a file with these thirteen (x,y) pairs of this temperature data.

```
x 0.0 2.0 4.0 6.0 8.0 10.0 12.0 14.0 16.0 18.0 20.0 22.0 24.0 y 6.3 4.0 6.6 10.9 14.6 19.1 24.3 25.7 22.9 19.5 15.9 10.3 5.4
```

Let $m = \min\{y\}$, $M = \max\{y\}$ and set a = 0.5*(M+m), b = 0.5*(M-m). Try to find some reasonable integer value for the parameter c in the interval [0, 24] so that the curve $y = a + b*\sin(2*\pi*(x-c)/24))$ becomes as close to the data as possible. Carry out the following steps:

(a) Read the data (x_j,y_j) , j=1,...,13, from the file [or copy these values in a vector] and compute the maximum and minimum temperatures M and m. Then compute a and b.

FILE: ~/MME/demo11/d06/d06.tex — 3. syyskuuta 2012 (klo 19.21).

(b) For each c = 0: 24 compute

$$A(c) = \sum_{j=1}^{13} (y_j - (a + b * \sin(2 * \pi * (x_j - c)/24)))^2$$
 ,

and choose the value of c that yields the minimal A(c).

- (c) With these values of the parameters a, b, c plot the curve $y = a + b * \sin(2 * \pi * (x c)/24))$ and the data points in the same picture.
- 3. To fit a circle (1) $(x-c_1)^2+(y-c_2)^2=r^2$ to n sample pairs of coordinates $(x_k,y_k), k=1,...,n$ we must determine the center (c_1,c_2) and the radius r. Now (1) \Leftrightarrow (2) $2xc_1+2yc_2+(r^2-c_1^2-c_2^2)=x^2+y^2$. If we set $c_3=r^2-c_1^2-c_2^2$, then the equation takes the form

$$2xc_1 + 2yc_2 + c_3 = x^2 + y^2$$
 .

Substituting each data point we get

$$\left[egin{array}{ccc} 2x_1 & 2y_1 & 1 \ dots & dots \ 2x_n & 2y_n & 1 \end{array}
ight]\left[egin{array}{c} c_1 \ c_2 \ c_3 \end{array}
ight] = \left[egin{array}{c} x_1^2 + y_1^2 \ dots \ x_n^2 + y_n^2 \end{array}
ight]$$

This system can be solved in the usual way for c = matrix/ rhs . Then $r=\sqrt{c_3+c_1^2+c_2^2}$. Apply this algorithm for the points generated by

```
r=0.5+0.5*rand(10,1);
theta=2*pi*rand(10,1);
clear x
clear y
x=3*r.*cos(theta);
y=3*r.*sin(theta);
```

Plot the data and the circle.

4. The number of participants of the weekly problem sessions of a mathematics course during the first six weeks were 21, 24, 17, 21, 14 and 17, respectively. Fit a model of the type

$$y = \lambda_1 \exp(-\lambda_2 x)$$

to this data and predict the number of participants in the 12th problem session.

Hint: It may (or may not) be a good idea to make a linear transform

y'=y/25, x'=x/12 for the fitting, and then use the program par-fit.m/Lectures/Section 2 and finally to transform back to the original variables.

- 5. Familiarize yourself with the program getpts.m and use it to plot a closed polygon in the plane. Compute also its area with polyarea.
- **6.** Consider the tabulated values x=0:0.2:3.2; y=d071f(c,d,x) of the function $d071f(x) = \sum_{j=1}^m c_j \sin(d_j*x)$ with $c=[1\ 2\ 3\ 2\ 1]$, $d=[3\ 2\ 1\ 2\ 2]$. The data is interpolated to the points x=0.0:0.05:3.2 by using two different methods; (a) interp1, (b) spline. Find the maximum error of each method by comparing the interpolation to the values of the function at these points.
