Outline

We define discrete convolution using periodic boundary conditions

Let $p \in \mathbb{R}^n$ and $s \in \mathbb{R}^n$. We call s the *signal* and p the *point spread function (PSF)*.

Convolution, denoted by $p * s \in \mathbb{R}^n$, is defined by the formula

$$(p * s)_j = \sum_{\ell=1}^{n} p_\ell s_{j-\ell}, \tag{1}$$

where $s_{j-\ell}$ is defined by periodic extension for the cases $j - \ell < 1$ and $j - \ell > n$. For example, $s_0 = s_n$ and $s_{-1} = s_{n-1}$ and $s_{n+1} = s_1$.

Step-by-step construction of the convolution vector (1) is shown in the following slides for a special case with $n = 10$. Note that only nonzero elements of $p \in \mathbb{R}^n$ are plotted. The elements $(p * s)_j$ are shown in blue color; the last slide (position 10) shows the complete vector $p * s \in \mathbb{R}^n$.

Outline

Given a PSF vector p, the mapping $\mathcal{A} : \mathbb{R}^n \to \mathbb{R}^n$ defined by $\mathcal{A}(s) = p * s$ is linear

Therefore, we can construct a $n \times n$ matrix A so that

$$\mathcal{A}(s) = As.$$

The following slides demonstrate the construction of the matrix A. Note that the structure of A is highly redundant as the same PSF elements appear many times.

The Matlab command `convmtx.m` is useful for building convolution matrices.
